

Agree as derivational operation

Its definition and discontents

Daniel Milway

dan.milway@gmail.com

6th April 2021

Abstract

Using the framework laid out by Collins and Stabler (2016), I formalize Agree as a syntactic operation. I begin by constructing a formal definition a version of long-distance Agree in which a higher object values a feature on a lower object, and modify that definition to reflect various several versions of Agree that have been proposed in the “minimalist” literature. I then discuss the theoretical implications of these formal definitions, arguing that Agree (*i*) muddies our understanding of the evolution of language, (*ii*) requires a new conception of the lexicon, (*iii*) objectively and significantly increases the complexity of syntactic derivations, and (*iv*) unjustifiably violates NTC in all its non-vacuous forms. I conclude that Agree, as it is commonly understood, should not be considered a narrowly syntactic operation.

1 Introduction

Being computational theories of grammar, minimalist P&P theories deal mainly in procedures which generate linguistic expressions from atoms in an incremental fashion. That is, these theory traffic in computational procedures that relate stage n of a derivation to stage $n + 1$ of that same derivation in a regular definite way. From this perspective, Merge is the crown jewel of these theories—it has been developed with the twin goals of (*a*) ensuring that for an arbitrary derivation stage, any application of Merge would have a single predictable result, even if that result is failure, while (*b*) maintaining its descriptive adequacy. Much of the current literature in minimalist P&P grammar, however, assumes the existence of a second core procedure, Agree, which, I argue in this paper, has yet to be sufficiently defined as a computational procedure.

The correct characterization of Agree ultimately depends on empirical and theoretical considerations and, while virtually the entire contemporary Agree literature focuses on the former to the exclusion of the

25 latter, this paper seeks to contribute to the latter.¹ The assertion that the Agree literature is primarily
 26 focused on empirical concerns to the exclusion of theoretical ones, seems to be contradicted by the sheer
 27 number of theories of Agree that have been proposed—Chomsky (2000) begins with what might be called
 28 Classical Agree, and scholars later propose Cyclic Agree (Béjar and Rezac 2009), Local Agree (Hornstein
 29 2009), Fallible Agree (Preminger 2014), and Upward Agree (Bjorkman and Zeijlstra 2014; Zeijlstra 2012),
 30 just to name those theories of Agree which have names. In fact, the proliferation of such theories is to be
 31 expected when inquiry is guided by the empirical rather than the theoretical, just as the proliferation of
 32 empirical predictions is to be expected when inquiry is guided by the theoretical.

33 This proliferation of theories of Agree is further exacerbated by the fact that, since its inception, Gen-
 34 erative Grammar has always had both derivational and representational expressions. In the theory used in
 35 *Aspects* (Chomsky 1965), for instance, (1) can be given three formal expressions—one derivational expression
 36 in (2), and two representational expressions in (3) and (4).

37 (1) Sincerity may frighten the boy.

38 (2) a. $S \rightarrow NP \frown Aux \frown VP$ (Chomsky 1965, p. 68)

39 $VP \rightarrow V \frown NP$

40 $NP \rightarrow Det \frown N$

41 $NP \rightarrow N$

42 $Det \rightarrow the$

43 $Aux \rightarrow M$

44 b. $M \rightarrow may$

45 $N \rightarrow sincerity$

46 $N \rightarrow boy$

47 $V \rightarrow frighten$

48 (3) $[S [NP Sincerity_N] [Aux may_M] [VP frighten_V [NP [Det the] boy_N]]]$

¹“Theory” and its derived terms are widely misunderstood within contemporary syntactic research. I take “theory” to refer to a logical system which is hypothesized to explain some domain of nature, and “theoretical” work to refer to work that investigates the internal logical properties of a theory. The work that is taken to fall under the umbrella of “theoretical syntax,” however, is more often than not data analysis work—*i.e.*, empirical work—which (*a*) does not involve quantitative analysis—as opposed to “corpus work”—and (*b*) ignores the method of gathering the analyzed data—to differentiate it from “experimental work” and “field work.” See Chametzky (1996) for related discussion.

49

(4)

50 Since Generative Grammar is a computational theory, the derivational expression of a given analysis has
 51 always been the ultimate expression. The representational expressions, on the other hand, are much more
 52 concise and accessible, so they have been overwhelmingly used as shorthands for the derivational expressions,
 53 but they are useful as short-hands only insofar as they are isomorphic with the derivational expressions.

54 These representational expressions become problematic, however, when they are augmented for the sake
 55 of clarity. For instance movement/Internal Merge can be represented without arrows as in (5), but more often
 56 arrows will be added for ease of understanding as in (6), though (5) and (6) are assumed to be equivalent.

57

(5)

58

(6)

59 It is, perhaps, understandable that Agree, commonly represented by arrows similar to movement arrows as
 60 in (7), is assumed to have the same level of theoretical underpinning as movement.

62 To date, though, there has been no proposal for a derivational expression of the arrow in (7). The task of
 63 this paper in part, then, is to remedy this oversight.

64 To that end, I will be expanding the formal grammar developed by Collins and Stabler (2016). I sketch
 65 out this grammar, which is based on a more-or-less contemporary theory within the minimalist program, in
 66 section 2, and extend it to include Agree in ???. While I focus on what I call Long-distance Downward Valuing
 67 (LDDV) Agree, I also discuss how my definitions could be adjusted to reflect other theories such as those
 68 that assume feature checking or upward valuation, as well as local varieties of Agree. In section 4 I consider
 69 the theoretical implications of my definition of Agree, including its relation to Merge, its computational
 70 complexity, and its relation to the No Tampering Condition. Finally, in section 5 I give some concluding
 71 remarks.

72 2 What does a definition look like?

73 Collins and Stabler (2016) provide a framework for formal definition. This formal definition uses sets and
 74 their basic predicates, relations, and operations (membership, subset, Set difference, etc) and finite sequences
 75 referred to as “pairs,” “triples,” and so on depending on their size. Using these formal notions, the grammar
 76 they define is such that a number of organizing principles of minimalist theories are provable as theorems of
 77 this system. I will be defining Agree in this framework, and in order to understand what it means to define
 78 a derivational operation, I must first lay out some basic definitions Starting with Universal Grammar (UG)
 79 in (8).

80 (8) Universal Grammar is a 6-tuple: $\langle \text{PHON-F, SYN-F, SEM-F, Select, Merge, Transfer} \rangle$

81 PHON-F, SYN-F, and SEM-F are universal sets of phonetic, syntactic, and semantic features, respectively;
 82 Select, Merge, and Transfer are operations. I will begin the outline of the formal grammar with the feature
 83 sets, postponing discussion of the operations for now. Collins and Stabler (2016) (hereafter C&S) also define
 84 the set PHON-F* as the set of all possible phonetic strings. These feature-sets are grouped together to form
 85 lexical items, which are grouped into a lexicon, which effectively defines individual grammars, as in (9)–(11).

86 (9) A lexical item is a triple: $\text{LI} = \langle \text{PHON, SYN, SEM} \rangle$

87 where SEM and SYN are finite sets such that $SEM \subset SEM-F$, $SYN \subset SYN-F$, and $PHON \in PHON-$
88 F^* .

89 (10) A lexicon is a finite set of lexical items.

90 (11) An I-Language is a pair $\langle Lex, UG \rangle$, where Lex is a lexicon and UG is Universal Grammar.

91 In order to capture the Copy/Repetition distinction, C&S introduce lexical item tokens, defined in (12),
92 which are the atoms of syntactic computation. C&S, also define several other useful terms using LI tokens.²

93 (12) A lexical item token is a pair: $LI_k = \langle LI, k \rangle$, where LI is a lexical item, and k is an integer.

94 (13) A lexical array is a finite set of lexical item tokens.

95 (14) X is a syntactic object iff:

- 96 i. X is a lexical item token, or
- 97 ii. X is a set of syntactic objects.

98 (15) Let A and B be syntactic objects, then B immediately contains A iff $A \in B$.

99 (16) Let A and B be syntactic objects, then B contains A iff

- 100 i. B immediately contains A, or
- 101 ii. for some syntactic object C, B immediately contains C and C contains A.

102 C&S then define a generative framework, wherein complex syntactic objects are derived in stages.

103 (17) A stage is a pair $S = \langle LA, W \rangle$, where LA is a lexical array and W is a set of syntactic objects. We
104 call W the workspace of S.

105 The operations Merge, Select, and Transfer operate on stages and derive new stages. Merge is binary set-
106 formation, Select moves lexical item tokens from the lexical array to the workspace, and Transfer converts
107 syntactic objects into interface objects. Merge and Select are rather simple, as shown in (18) and (19).
108 Transfer, on the other hand, is more complicated—C&S devote 5 sections of their paper to developing its
109 definition—and, quite frankly, irrelevant to our discussion here. I will therefore omit the definition of Transfer
110 from this paper

111 (18) Given any two distinct syntactic objects A, B, $Merge(A, B) = \{A, B\}$.

112 (19) Let S be a stage in a derivation $S = \langle LA, W \rangle$.

113 If lexical token $A \in LA$, then $Select(LA, S) = \langle LA - \{A\}, W \cup \{A\} \rangle$

114 Thus, we can define the central notion of derivation in (20)

²See Collins and Groat (2018) for a survey of the various approaches to capture the Copy/Repetition distinction.

- 115 (20) A derivation from lexicon L is a finite sequence of stages $\langle S_1, \dots, S_n \rangle$, for $n \geq 1$,
 116 where each $S_i = \langle LA_i, W_i \rangle$, such that
- 117 i. For all LI and k such that $\langle LI, k \rangle \in LA_1$, $LI \in L$,
 - 118 ii. $W_1 = \{\}$ (the empty set),
 - 119 iii. for all i , such that $1 \leq i < n$, either
 - 120 (derive-by-Select) for some $A \in LA_i$, $\langle LA_{i+1}, W_{i+1} \rangle = \text{Select}(A, \langle LA_i, W_i \rangle)$, or
 - 121 (derive-by-Transfer) . . . , or
 - 122 (derive-by-Merge) $LA_i = LA_{i+1}$, and the following conditions hold for some A, B :
 - 123 a. $A \in W_i$
 - 124 b. Either A contains B or W_i immediately contains B , and
 - 125 c. $W_{i+1} = (W_i - \{A, B\}) \cup \{\text{Merge}(A, B)\}$

126 C&S's formalization is open for some refinements, such as those that Chomsky (2020) suggests, and
 127 extensions, but it provides us with a framework for those refinements and extensions. In order to add Agree
 128 to the formal grammar, for instance, we would need to define it as a function from stages to stages to be
 129 added as a derive-by-Agree clause to (20), and in order to define such a function, as we shall see, we will
 130 need a formal definition of features.

131 3 Defining Agree

132 Agree can be very broadly described as an operation that modifies a syntactic object X iff X stands in a
 133 particular formal/structural relation and a particular substantive relation with another syntactic object Y .
 134 So, in order to define Agree, we must formalize (a) the formal/structural prerequisite—Probe or Search—(b)
 135 the substantive prerequisite—Match—and (c) the process of modifying the object in question—Value or
 136 Check—each of which has, in a sense, been the focus of its own debate in the literature. As a starting
 137 point, I will formalize Long-Distance Downward Valuation Agree (LDDV-Agree), which is more or less the
 138 version of Agree put forth by Wurmbrand (2014) and which has the following properties. LDDV-Agree is
 139 long-distance in that it does not require a strictly local relation between the Agreeing objects, rather the
 140 Probe and Goal, as they are commonly called, stand in a c-command-plus-relativized-minimality relation as
 141 specified in (21).

- 142 (21) A Probe P and Goal G can Agree iff, P c-commands G , G Matches P , and there is no head H such
 143 that H Matches P , P c-commands H and H c-commands G .

144 LDDV-Agree is downward in the sense that it modifies the c-commanded Goal, and it is valuation-based in
 145 the sense that the Goal is modified by converting one of its unvalued feature into a valued one as specified
 146 in (22) and (23).

147 (22) A Goal G Matches a Probe P for feature F iff P has $[F:val]$ and G has $[F: _]$

148 (23) If P and G Agree for feature F then $[F: _]$ on G becomes $[F:val]$

149 The first thing we must do, is formalize the notion of “feature” as used here. By (8), there are three sets
 150 of features in Universal Grammar—PHON-F, SYN-F, SEM-F. Setting aside PHON-F as irrelevant to the
 151 current paper, our task is to formalize the members of SYN-F and SEM-F. Generally, a given syntactic or
 152 semantic feature is describable with reference to its interpretability, its type, and its value (or lack thereof).
 153 Interpretability can be taken care of by simple set membership—interpretable features are members of SEM-
 154 F, uninterpretable features are members of SYN-F—leaving us with type and value. We can define features,
 155 then, as in (24).

156 (24) A *feature* is a pair $\langle F, v \rangle$, where v is an integer. F is called the *feature type*, v is the *feature value*.

157 (25) For all feature types F , $\langle F, 0 \rangle$ is an *unvalued* F feature.

158 (26) For lexical item $LI = \langle PHON, SYN, SEM \rangle$, feature F_v is a *feature of* LI , iff $F_v \in SYN$ or $F_v \in SEM$.

159 (27) For lexical item token $LI_k = \langle LI, k \rangle$, feature F_v is a *feature of* LI_k , iff F_v is a feature of LI .

160 The choice to formalize feature values as integers is made only to allow for a perspicuous way of defining
 161 unvalued features. We could use any type of discrete symbol to represent values, provided he had a special
 162 symbol for “unvalued.”

163 We can define Match as in (28).

164 (28) For any two lexical item tokens P, G feature type F ,

165 $Match(P, G, F) = 1$ iff for feature value $v \neq 0$ $\langle F, v \rangle$ is a feature of P and $\langle F, 0 \rangle$ is a feature of G .

166 Value is essentially a replacement operation—operating on a lexical item token, swapping an unvalued feature
 167 with a valued counterpart. This is defined in (29).

168 (29) For lexical item token $LI_k = \langle \langle SEM, SYN, PHON \rangle, k \rangle$, and feature $\langle F, v \rangle$,

169 $Value(LI_k, \langle F, v \rangle) = \langle \langle SEM, (SYN - \{ \langle F, 0 \rangle \}) \cup \{ \langle F, v \rangle \}, PHON \rangle, k \rangle$

170 The last portion of Agree to be defined is Probe, which is an instance of “Minimal Search” (Chomsky 2004)
 171 an algorithm that requires some discussion

172 **3.1 Minimal Search**

173 The term Minimal Search, as its usually used in minimalist syntactic theory, refers to an algorithm that
 174 retrieves the “highest” object in a structure that meets some particular criterion. In the case of Probe, that
 175 criterion is Match as defined in (28). In order to properly define such an algorithm we must first consider
 176 some test cases as follows.

177 Each case is a complex abstract syntactic object containing two objects—G and H—each of which meets
 178 the search criterion. Each case is represented both as a binary set as constructed by Merge and a binary
 179 tree. The first case in (30) is the most straightforward—G asymmetrically c-commands H, so Minimal Search
 180 retrieves G and not H.

181 (30) **Case 1:** G is retrieved

182 a. $\{X, \{\mathbf{G}, \{\mathbf{Y}, \mathbf{H}\}\}\}$

183 b.

184 The second case in (31) is slightly more complicated—G does not c-command H, but Minimal Search should
 185 retrieve G because it is immediately contained in an object that asymmetrically c-commands H.

186 (31) **Case 2:** G is retrieved.

187 a. $\{X, \{\{\mathbf{G}, Y\} \{\{\mathbf{H}, Z\}, W\}\}\}$

188 b.

189 Other cases, though, will give ambiguous results. These are cases in which G and H are equidistant from the
 190 root. In (32), for instance G and H are siblings, while in (33) they are immediately contained, respectively,
 191 by siblings.

192 (32) **Case 3:** Both G and H are retrieved.

193 a. $\{X, \{\mathbf{G}, \mathbf{H}\}\}$

194 b.

195 (33) **Case 4:** Both G and H are retrieved.

196 a. $\{X \{\{\mathbf{G}, \mathbf{Y}\}, \{\mathbf{H}, \mathbf{Z}\}\}\}$

197 b.

198 Our goal, then, is to construct an algorithm that has the above-defined results. There are two broad classes
199 of search algorithms appropriate to our task—Depth-First Search (DFS) and Breadth-First Search (BFS).
200 DFS, starts at the root of an object and searches to a terminal node before backtracking, as represented in
201 (34), where the arrows and the numbers indicated the search order.

202 (34)

203 A DFS algorithm can be made minimal by designing it to stop as soon as it finds a node that meets its
204 criterion. So, a Minimal DFS on Case 1 would be proceed as in (35) selecting.

205 (35)

206 However in an ambiguous case, like Case 4, a Minimal DFS will incorrectly retrieve just a single object as
 207 shown in (36).

209 A Minimal DFS algorithm, then is over-definite—it gives a definite result where we expect an ambiguous
 210 one.

211 There is also a deeper problem with DFS as applied to syntactic objects, and that is its reliance on linear
 212 order as well as structure. In the examples above, whenever the algorithm reaches a branching node, it takes
 213 the left branch first. If it, instead, took the right branch first, the result would be different—in both (35)
 214 and (36), a right-to-left Minimal DFS would retrieve H rather than G. The problem is made worse by the
 215 fact that, the structures that we are searching are constructed by Merge and, therefore, do not have a linear
 216 order. In order for our algorithm to make a decision at a “branch,” then, it would have to be a random
 217 decision. Therefore, the result of a DFS for a given syntactic object may be different each time it is run.
 218 Given these issues, I will set aside DFS.

219 Breadth-first Search (BFS) algorithms, on the other hand, searches neighbour nodes before proceeding
 220 lower in the tree as represented in (37), where the arrows and the numbers indicated the search order.

222 Again, this can be made minimal by requiring that the algorithm stop immediately upon finding an object
 223 that matches the search criterion. A Minimal BFS on Case 2, then, is represented in (38).

224 (38)

225 Like the Minimal DFS, the Minimal BFS, as represented in (37) and (38) assumes that nodes are linearly
 226 ordered, even if that order is arbitrary. Unlike the Minimal DFS, the order of the neighbour nodes does not
 227 matter, at least for definite cases like Case 1 and Case 2. To demonstrate this, consider the reverse version
 228 of (38) in (39).

229 (39)

230 In an ambiguous case, though, Minimal BFS suffers the same fate as Minimal DFS—it is over-definite. So,
 231 in Case 3, Minimal BFS will wrongly retrieve either G or H depending on the ordering of nodes, as shown
 232 in (40) and (41).

233 (40)

234 (41)

235 This flaw, however, can be overcome if, instead of traversing each node, we treat the sets of neighbour nodes
 236 as tiers, as in (42).

237 (42)

238 Minimal Tiered BFS, then, would visit each tier and extract the subset of that tier whose members all
 239 matched the search criterion, and stop as soon as it extracts a non-null subset. Thus we can define a definite
 240 search result as in (43), an ambiguous search result as in (44), and a failed search as in (45).

241 (43) For a syntactic object SO and criterion P, $\text{Search}(\text{SO}, P)$ is definite iff $|\text{Search}(\text{SO}, P)|=1$

242 (44) For a syntactic object SO and criterion P, $\text{Search}(\text{SO}, P)$ is ambiguous iff $|\text{Search}(\text{SO}, P)| > 1$

243 (45) For a syntactic object SO and criterion P, $\text{Search}(\text{SO}, P)$ is failed iff $\text{Search}(\text{SO}, P) = \{\}$

244 Minimal Tiered BFS, then, will be our choice of Search algorithm. The next step is to formally define it.

245 In order to define Search, then, we need to be able to properly generate search tiers. So, for instance,
 246 the tiers for (31) are given in (46)

247 (46) Tier 1 = $\{X, \{\{\mathbf{G}, Y\}, \{\{\mathbf{H}, Z\}, W\}\}\}$

248 Tier 2 = $\left\{ \begin{array}{l} \{\mathbf{G}, Y\}, \\ \{\{\mathbf{H}, Z\}, W\} \end{array} \right\}$

249 Tier 3 = $\left\{ \begin{array}{l} \mathbf{G}, Y, \\ \{\mathbf{H}, Z\}, \\ W \end{array} \right\}$

250 Tier 4 = $\{\mathbf{H}, Z\}$

251 Tier 5 = $\{\}$

252 For a given Tier T_i , we can generate T_{i+1} by first removing all the terminal nodes from T_i and performing
 253 what is called an arbitrary union which is defined in (47).

254 (47) For a set $X=\{x_0, \dots, x_n\}$ the arbitrary union of X, $\bigcup X=x_0 \cup \dots \cup x_n$.

255 Therefore we can define a procedure NextTier in (48) and with it, Search in (49).

256 (48) For T, a set of syntactic objects, $\text{NextTier}(T)=\bigcup\{\text{SO}\in T: \text{SO is not a lexical item token}\}$.

257 (49) For S , a set of syntactic objects, and Crit , a predicate of lexical item tokens,

$$258 \quad \text{Search}(S, \text{Crit}) = \begin{cases} \{\} & \text{if } S = \{\} \\ \{\text{SO} \in S : \text{Crit}(\text{SO}) = 1\} & \text{if } \{\text{SO} \in S : \text{Crit}(\text{SO}) = 1\} \neq \{\} \\ \text{Search}(\text{NextTier}(S), \text{Crit}) & \text{otherwise} \end{cases}$$

259 Probe , then is a special type of Search , where the search criterion is based on Match , is shown in (50).

260 (50) For F , a feature type, and SO , a syntactic object that immediately contains P , a lexical item token,

$$261 \quad \text{Probe}(\text{SO}, P, F) = \text{Search}(\text{SO}, (\lambda x) (\text{Match}(P, x, F)))$$

262 With our definition of Probe in place, we can turn to our final definition of Agree which I turn to shortly in
263 section 3.2.

264 3.1.1 The appeal of DFS and attempts to rescue it

265 Although DFS is empirically/descriptively inadequate—given the theoretical assumptions of this paper—it
266 retains a certain theoretical and aesthetic appeal. This appeal may come from the fact that it can be given
267 a simple recursive definition using only the primitive concepts such as set-membership. In contrast, BFS
268 as defined in (49) requires the definition of the ad hoc notion of a tier, which I have implicitly defined in
269 (48) using an arbitrary union—a function whose computational definition is likely more complex than the
270 \cup symbol lets on.

271 It's no surprise, then, that Branan and Erlewine (forthcoming) and Preminger (2019) do not embrace
272 BFS as a minimal search algorithm, with Preminger defining a version of DFS and Branan and Erlewine
273 making no firm decision between the two options. This is not to say that the authors are not aware of the
274 problems of DFS that I outline above.³ On the contrary, Branan and Erlewine explicitly addresses these
275 issues and they and Preminger both argue that the weaknesses of DFS can be avoided if certain parts of
276 a structure are inaccessible to Search , however neither provide a principled way of so restricting the DFS
277 algorithm—at least, not given the theoretical assumptions of the current paper. Preminger proposes that
278 specifiers are not searched, while Branan and Erlewine suggest that left-branches might not be searched.
279 Both of these proposals, though, depend on an assumption that syntactic objects produced by Merge are
280 inherently asymmetric, while the present paper assumes the exact opposite.

281 It would be a mistake, though, to declare DFS fully discredited on the basis these arguments. The
282 theoretical and aesthetic appeal that I describe above must be answered and the hypotheses that Branan
283 and Erlewine and Preminger put forth to rescue it have empirical backing. What is needed, though, is a
284 principled theory that predicts rather than declares, for example, that the internal structure of a specifier

³*cf* Ke (2019, pp. 47–49) for a different expression of these problems.

285 is inaccessible to minimal search. Since I know of no such theory, I will assume that DFS is inadequate as a
 286 model of minimal search.

287 3.2 A formal definition of Agree

288 If and when an instance of Probe retrieves a goal, that goal must be modified—at least according to most
 289 versions of Agree.⁴ More precisely, the Goal must be modified in place. That is, if goal G is in position Q
 290 in stage S_i , then the modified goal G' must be in position Q in stage S_{i+1} . Furthermore, if copies of G are
 291 in multiple positions (Q, Q', Q''...) in S_i , then copies of G' must be in those same positions in S_{i+1} . In
 292 order to do this we must traverse the syntactic object in question and replace every instance of G with G' ,
 293 the result of Value. Thus we can define Agree as in (51).

294 (51) For lexical item P, syntactic object $SO=\{P, \dots\}$, and feature type F, and lexical-item G, the sole
 295 member of $\text{Probe}(SO,P,F)$,

$$296 \quad \text{Agree}(SO, P, F_v) = \begin{cases} \text{Value}(SO, \langle F, v \rangle) \text{ if } SO=G \\ \text{SO if SO is a lexical item token} \\ \text{Merge}(\text{Agree}(A, P, F_v), \text{Agree}(B, P, F_v)) \text{ for } A, B \in SO \text{ such that } A \neq B \end{cases}$$

297 As defined, Agree is a non-minimal DFS—it has no notion of tiers, only differentiating lexical item tokens
 298 from complex syntactic objects. While minimalist considerations might suggest that a single search algorithm
 299 be selected for the grammar, DFS is ill-suited for Probe, as discussed above, and DFS is ill-suited for Agree.
 300 The reason we cannot use DFS for Agree, is because Agree must retain the structure of its inputs—it needs
 301 to put things back where it found them—something that DFS cannot do. Consider, for instance, Tier 3 in
 302 (46)—a 4-member set which could be reconstructed into a proper syntactic object a number of ways. Thus,
 303 we need both DFS and BFS to be active in the grammar.

304 We have arrived at a formal definition of one variety of Agree (LDDV-Agree) which we will use in the
 305 the following section as a basis for defining other varieties,

306 3.3 Upward Valuation

307 In defining a Downward Valuation Agree, we considered syntactic objects such as the one schematized in
 308 (52) which immediately contain lexical item tokens bearing a valued feature F_v and which contain a lexical
 309 item token bearing an unvalued feature F_0 .

310 (52) $\{P_{F:v}, \{\dots G_{F:0}\}\}$

⁴If we wished to define Agree purely as a relation—*i.e.* an n -place predicate ($n>1$)—we could simply define it as $\text{Agree?}(P, G, F)$ iff $\text{Probe}(P, F) = G$.

311 In an Upward Valuation, the relevant features of P and G are swapped, as in (53).

$$312 \quad (53) \quad \{P_{F:0}, \{\dots G_{F:v}\}\}$$

313 In order to capture Upward Valuation, then we need first modify the Match criterion of Probe as in (54),
314 moving P to the second argument position.

$$315 \quad (54) \quad \text{For } F, \text{ a feature type, and } SO, \text{ a syntactic object that immediately contains } P, \text{ a lexical item token,} \\ 316 \quad \text{Probe}_{UV}(SO, P, F) = \text{Search}(SO, (\lambda x) (\text{Match}(x, P, F))).$$

317 Thus, Probe_{UV} gives a definite result $\{G\}$ only if P contains an unvalued F feature and G contains a valued
318 F feature. Since, by definition, the relevant unvalued feature in Agree_{UV} is at the top of the structure,
319 we might think that no exhaustive DFS is required. Unfortunately, though, the same concern with valuing
320 copies is with us—just because a lexical item token is at the top of a tree doesn't mean there isn't a copy of
321 it at the bottom. Therefore, our definition of Agree_{UV} in (55) look similar to that in (51).

$$322 \quad (55) \quad \text{For lexical item } P, \text{ syntactic object } SO=\{P, \dots\}, \text{ and feature type } F, \text{ and lexical-item } G, \text{ the sole} \\ 323 \quad \text{member of } \text{Probe}_{UV}(P,F) \text{ and } v \text{ the value of the } F \text{ feature on } G, \\ 324 \quad \text{Agree}_{UV}(SO, P, F_v) = \begin{cases} \text{Value}(SO, \langle F, v \rangle) \text{ if } SO=P \\ \text{SO if } SO \text{ is a lexical item token} \\ \text{Merge}(\text{Agree}_{UV}(A, P, F_v), \text{Agree}_{UV}(B, P, F_v)) \text{ for } A, B \in SO \text{ such that } A \neq B \end{cases}$$

325 3.4 Feature Checking

326 Versions of Agree that causes feature checking rather than valuation assume that all formal features—*i.e.*,
327 members of SYN-F—are valued, but must be checked by Agree. In order to formalize such a feature checking
328 operation, $\text{Agree}_{\checkmark}$, we must reformulate our notion of features and our Match predicate, and replace Value
329 with Check. Formal features and their related notions, then, are defined as in (56) and (57), with semantic
330 features retaining their definition in (24).

331 (56) A *formal feature* is a triple $\langle c?, F, v \rangle$, where $c?$ is 1 or 0 and v is an integer. F is called the *feature*
332 *type*, v is the *feature value*.

333 (57) For all feature types F and values v , $\langle 0, F, v \rangle$ is an *unchecked* F_v feature, and $\langle 1, F, v \rangle$ is *checked*
334 F_v feature.

335 $\text{Match}_{\checkmark}$, then, compares a semantic feature of one lexical item token with a formal feature of another
336 succeeding if both features have the same type and value and the formal feature is unchecked, as defined in

$$337 \quad (58)$$

338 (58) For any two lexical item tokens P, G feature type F and value v,
 339 $\text{Match}_{\checkmark}(P, G, F) = 1$ iff $\langle F, v \rangle$ is a feature of P and $\langle 0, F, v \rangle$ is a feature of G.

340 Finally, Check is a simple matter of flipping a 0 to a 1 as in (59).

341 (59) For a formal feature $F_v = \langle c?, F, v \rangle$,
 342 $\text{Check}(F_v) = \langle 1, F, v \rangle$.

343 These newly defined functions can be slotted into our formalized definitions of Agree, perhaps with a few
 344 other alterations, which I leave as an exercise for the interested reader.

345 3.5 Local Agree

346 Early minimalist theories of agreement (*e.g.* Chomsky 1993) continued the GB assumption that agreement
 347 was limited to a spec-head relation. So, for example, subject-predicate agreement was assumed to occur
 348 because the subject moves to the specifier of the predicate head (T or I), in contrast to later theories in
 349 which subjects move because they agree. Similarly, Case licensing, in these theories, is usually taken to occur
 350 under a spec-head relation. In this section, I will formalize this conception of Agree.

351 On its surface, Local Agree, as described above, has the advantage of not requiring an arbitrary search of
 352 the entire derived expression. Instead, the search is strictly and specifically limited to the very top of object.
 353 The canonical case of spec-head agreement is the finite subject merged with the finite predicate, shown in
 354 (60)

355 (60) $\text{TP} = \{\{D, \dots\}, \{T, \dots\}\}$

356 Restricting our discussion to Case, we can see that the Agree operation is an interaction between the lexical
 357 item token immediately contained in one member of TP and the lexical item token contained in the other
 358 member of TP. We can define $\text{Probe}_{\text{Local}}$, then, as in (61).

359 (61) For feature type F, lexical item tokens P and G, and syntactic object $\text{SO} = \{X, Y\}$,
 360
$$\text{Probe}_{\text{Local}}(\text{SO}, P, F) = \begin{cases} G & \text{if } P \in X, G \in Y, \text{ and } \text{Match}(P, G, F) \\ \text{undefined} & \text{otherwise} \end{cases}$$

361 Since spec-head structures, especially those associated with Case and agreement, are often formed by Internal
 362 Merge, our final version of $\text{Agree}_{\text{Local}}$, much like long-distance Agree, will need to replace every instance of
 363 the object being valued/checked. Therefore, our final version of $\text{Agree}_{\text{Local}}$, like our baseline Agree in (51),
 364 will be recursively defined—the main difference between the two will be their respective Probe prerequisites.

365 Other changes must be made to Agree though. Recall, for instance, that, in order to account for am-
 366 biguous searches, Search was defined in (49) such that its output was a set of lexical item tokens, and Agree

367 was defined in (51) so that it only proceeds when the output of Probe—a species of Search—is a singleton
 368 set. Probe_{Local} does not have to account for ambiguous searches—either the appropriate G is the head of
 369 the specifier of P, or it isn't. Therefore, the Probe prerequisite of Agree_{Local} must be rewritten. This is a
 370 relatively minor rewrite, but a rewrite nonetheless.

371 3.6 Summary

372 In this section, I provided a formal definition of one particular conception of Agree—Long-Distance Downward
 373 Valuation Agree—by first breaking it into individual pieces—Probe, Match, Value—which I gave formal
 374 definitions, and then assembling those definitions in such a way as they define Agree. I then discussed a few
 375 alternative conceptions of Agree, showing how they could be defined by altering the previous definitions as
 376 minimally as possible. This description of the definition process might suggest that Agree is modular—that
 377 it consists of several independent operations that can be mixed and matched—but this is not the case.
 378 Rather, while the discussion of each alternative tended to focus on a single operation, the changes to that
 379 operation was such that it necessitated minor modifications to Agree as a whole. Agree, then, does seem to
 380 be real operation, albeit a rather complex one, as I will demonstrate in the next section.

381 4 UG_{Agree}

382 With the Agree operation properly formalized, we can give a definition of UG_{Agree} in (62) and derivation in
 383 (63).

384 (62) Universal Grammar is a 7-tuple: $\langle \text{PHON-F, SYN-F, SEM-F, Select, Merge, Transfer, Agree} \rangle$

385 (63) A derivation from lexicon L is a finite sequence of stages $\langle S_1, \dots, S_n \rangle$, for $n \geq 1$,

386 where each $S_i = \langle LA_i, W_i \rangle$, such that

387 i. For all LI and k such that $\langle LI, k \rangle \in LA_1$, $LI \in L$,

388 ii. $W_1 = \{\}$ (the empty set),

389 iii. for all i , such that $1 \leq i < n$, either

390 (derive-by-Select) for some $A \in LA_i$, $\langle LA_{i+1}, W_{i+1} \rangle = \text{Select}(A, \langle LA_i, W_i \rangle)$, or

391 (derive-by-Transfer) . . . ,

392 (derive-by-Merge) $LA_i = LA_{i+1}$, and the following conditions hold for some A,B:

393 a. $A \in W_i$

394 b. Either A contains B or W_i immediately contains B, and

395 c. $W_{i+1} = (W_i - \{A, B\}) \cup \{\text{Merge}(A, B)\}$

396 (derive-by-Agree) or $LA_i = LA_{i+1}$ and the following conditions hold for some SO, P, G and F:

- 397 a. $SO \in W_i$
- 398 b. SO immediately contains P
- 399 c. $\text{Probe}(SO, P, F) = \{G\}$
- 400 d. $W_{i+1} = (W_i - \{SO\}) \cup \{\text{Agree}(SO, P, G, F)\}$

401 This definition of a derivation uses the names of its procedures, but in the case of Merge and Select, one could
402 just as easily expand them to give their full definition in intension. Agree is ultimately defined recursively,
403 as is its prerequisite Probe, so such an expansion is not possible. This is a crucial difference between Agree
404 and the other generative operations. While we could conceivably rank Select, Internal-, and External-Merge
405 by complexity, such a ranking would be one of degree. Agree, however, with its recursive definition is a
406 different kind of operation. Interestingly, C&S also define Transfer recursively. It follows then that Transfer
407 should also be considered a different kind of operation—a conclusion also predicted by the fact that Transfer
408 is generally considered an operation of the interfaces rather than Narrow Syntax.

409 Beyond its recursive definition, there are a number of properties that set Agree apart from its fellow
410 operations. First, since performing Agree on a syntactic object entails searching the object, modifying certain
411 constituents, and putting the object back together, Agree entails Merge. This is reflected in definitions (51)
412 and (55) and concurs with Hornstein (2009, pp. 126–154) who notes that the minimal c-command relation
413 required by Agree (Specifically non-local Agree, or AGREE in his terminology) is exactly the same as the
414 one that is assumed to hold in all cases of Internal-Merge (which he calls “Move”). Hornstein’s critique, that
415 Agree and Internal-Merge are redundant, is actually complementary to the fact that Agree as defined entails
416 Merge. The former suggests that either Agree or Internal Merge should be eliminated, while the latter rules
417 out eliminating Internal-Merge.

418 Agree being dependent on Merge also raises a biolinguistic critique. Chomsky (2020, and elsewhere)
419 proposes the following evolutionary narrative of the language faculty. The faculty of language (*i.e.*, Merge)
420 evolved quite suddenly 40 000–50 000 years ago in humans as a purely internal instrument of thought. It
421 was only later, after humans began migrating out of Africa, that externalized language emerged (Huybregts
422 2017). This narrative explains the fact that much, perhaps most, of our use of language is strictly internal
423 to our individual minds—that language is independent of externalization. Or, put another way, this story
424 of the evolution of the language faculty correctly predicts that the set of externalized—*i.e.*, spoken, signed,
425 written—linguistic objects (LOs) is a subset of the set of linguistic objects as in figure 1. The fact that Agree
426 entails Merge suggests either that it emerged as part of externalization—which I address later—or it emerged
427 separately from both Merge and Externalization. The latter option includes two suboptions—either Agree

Figure 1: The relation between LOs and externalized LOs

428 emerged as an augmentation to Merge and Externalization emerged as an augmentation to Merge+Agree, or
 429 Agree and Externalization emerged as separate augmentations to Merge. The former option would predict
 430 that the set of Agreeing LOs is a subset of the set of LOs and a superset of the set of externalized LOs, as
 shown in figure 2. The latter option would predict that the set of Agreeing LOs and the set of Externalized

Figure 2: A possible relation between LOs, Agreeing LOs and externalized LOs

431

LOs are each a subset of the set of LOs, though neither is a subset of the other, as shown in figure 3. Note

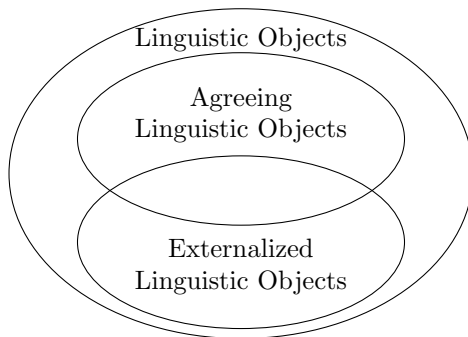

Figure 3: A possible relation between LOs, Agreeing LOs and externalized LOs

432

433 that the overlap between Agreeing LOs and Externalized LOs is not theoretically or logically guaranteed,
 434 but rather is an empirical fact. Each of these options predicts that non-external LOs can be divided into
 435 Agreeing and non-Agreeing LOs, while the latter further predicts that external LOs show the same division.
 436 These are, in principle, empirical predictions albeit not yet practically so, as it is not clear what non-Agreeing
 437 LOs, either internal or externalized, look like in this context.

4.1 The Non-Closure of Agree

Since a computational procedure is essentially the repeated application of an operation, or set of operations, with each application providing the input for the following application, the domain of a given computational operation must be closed under that operation. In the case of our syntactic derivations, our domain is the set of stages, which C&S demonstrate are closed under derive-by-Select and derive-by-Merge. I have thus far been assuming that it is also closed under derive-by-Agree, but that assumption is perhaps not strictly true, under our present definitions.

As defined, derive-by-Agree is a function from stages to stages that modifies a stage's workspace, by performing Agree on a syntactic object in that workspace. Therefore, the set of stages is closed under derive-by-Agree iff the set of syntactic objects is closed under Agree. For its part, Agree operates on a given syntactic object SO by applying Value to SO if SO is an appropriate lexical item token, or to the appropriate lexical item tokens contained in SO otherwise. Therefore the set of syntactic objects is closed under Agree iff the set of lexical item tokens is closed under Value. We need only consider a simple instance of Value to see that this is not the case.

Consider the lexical item token X_k , defined in (64), which has only one syntactic feature, $[F:0]$.

$$(64) \quad X_k = \langle \langle \text{PHON}_X, \{ \langle F, 0 \rangle \}, \text{SEM}_X \rangle, k \rangle$$

where $\text{PHON}_X \in \text{PHON-F}^*$, $\text{SEM}_X \subset \text{SEM-F}$, k is an integer, and $\langle F, 0 \rangle \in \text{SYN-F}$.

What about the result of applying Value to X_k , given in (65)?

$$(65) \quad \text{Value}(X_k, \langle F, v \rangle) = \langle \langle \text{PHON}_X, \{ \langle F, v \rangle \}, \text{SEM}_X \rangle, k \rangle$$

where v is a non-zero integer.

Since PHON_X , SEM_X , and k are unchanged, the new object is a lexical item token iff $\langle F, v \rangle \in \text{SYN-F}$. That is, the set of lexical item tokens is closed under Value only if the universal set of syntactic features in UG_{Agree} contains both valued and unvalued features. However, if we hypothesize that SYN-F contains valued and unvalued features, we are faced with something of a theoretical quandary. In this system, language acquisition is a process of constructing lexical items from universal feature sets so that they match tokens in the primary linguistic data. The basic premise of Agree theory, though, is that unvalued features cannot surface. If this is the case, then there are no tokens of unvalued features in the primary linguistic data. Why, then, would a language acquirer ever construct a lexical item with an unvalued feature?

To take a concrete case, consider the English third person singular present agreement morpheme *-s*. Taking for granted that an English acquirer can give a proper phonological and semantic analysis of the morpheme, there are two possible lexical items they could construct, given in (66) and (67).

	Closed under Merge	Closed under Select	Closed under Agree
Syntactic Objects	Yes	Yes	No
Valued Syntactic Objects	Yes	Yes	No
Syntactic Objects \cup Valued Syntactic Objects	Yes	Yes	Yes

Table 1: The closure properties of Merge, Select, and Agree

469 (66) $\langle [z], \{\langle \pi, 3 \rangle, \langle \#, 1 \rangle\}, \{\langle T, 1 \rangle\} \rangle$

470 (67) $\langle [z], \{\langle \pi, 0 \rangle, \langle \#, 0 \rangle\}, \{\langle T, 1 \rangle\} \rangle$

471 The lexical item in (66), would be the result of a surface analysis of the data, while the one in (67) would
472 require a deeper analysis. So, in order to predict the acquisition of (67), we would need a theory of acquisition
473 that systematically does not match lexical items to surface phenomena.

474 Supposing on the contrary, that we bite the bullet and allow for valued lexical items to be acquired,
475 even if we stipulate that unvalued lexical items are also acquired, economy considerations would suggest
476 that those unvalued lexical items would never be used. In such a situation, every complex expression of
477 a language would be derivable in at least two ways—one that begins with a lexical array containing only
478 unvalued lexical item tokens and one that begins with a lexical array containing only valued lexical item
479 tokens.⁵ Each derivation will have the same number of Merge steps and Select steps but the first derivation
480 will also have Agree steps, while the second will have no Agree steps. Thus, for any expression of a language,
481 the second type of derivation will always have fewer steps than the first. So paradoxically, expanding our
482 universal feature sets to allow for Agree in this way, effectively rules out Agree.

483 To get out of this paradox, we could simply expand the domain of Merge, Select, and Agree to encompass
484 the union of the set of lexical items and the set of valued lexical items. This would fix the problem in an
485 engineering sense—we would be able to derive expressions in our formalism—but it would only serve to
486 formalize the theoretical concerns that I have been addressing. It would do so because it highlights the fact
487 that UG with only Merge and Select is a fully self-consistent system whose domain must be augmented to
488 accommodate Agree. This situation, which can be seen in table 1, is hardly surprising considering the very
489 nature of the operations—Merge combines objects without changing them, Select rearranges objects without
490 changing them, Agree changes objects.

⁵Setting aside the possibility of lexical items without syntactic features.

491 4.2 Agree as a prerequisite for Merge

492 Early in the minimalist program, Chomsky (2000) proposed that Agree was a prerequisite for Move—that
493 Move was a reflex of Agree. Merge—what we now call External Merge—on the other hand, was free to apply
494 without Agree. Once Internal Merge was discovered, though, theorists were faced with a dilemma—if Merge
495 and Move were truly a single operation, they couldn't very well have different prerequisites. There are two
496 ways out of this dilemma—either all instances of Merge are free, or all instances of Merge require Agree.⁶
497 Since C&S's formalization and my extension of it assume that all operations, except perhaps Transfer, are
498 free, I will not discuss the former way out of the dilemma. Rather, in this section, I will discuss the barriers
499 to modifying the formal grammar to make Agree a prerequisite for Merge.

500 The principle barrier to making Agree a prerequisite for Merge is that, as defined in (63), the derivation
501 is a computational procedure and, therefore, is strictly incremental. That is, the validity of a given stage
502 S_n ($n \neq 1$) depends solely on its form and the form of the immediately preceding stage S_{n-1} . Requiring every
503 instance of Merge to be preceded by an instance of Agree, however, would mean that the validity of a stage
504 S_n ($n \neq 1$) depends on its two preceding stages S_{n-1} and S_{n-2} . A derivation, then, would need memory, albeit
505 a very small amount of it.

506 On its face, this does not seem to be an insurmountable barrier, but as we shall see, it will end up ruling
507 out the first instance of Merge in any derivation. To begin with, we reformulate our definition of derivation
508 by adding a line in our derive-by-Merge clause in (68).

509 (68) A derivation from lexicon L is a finite sequence of stages $\langle S_1, \dots, S_n \rangle$, for $n \geq 1$,

510 where each $S_i = \langle LA_i, W_i \rangle$, such that

511 i. For all LI and k such that $\langle LI, k \rangle \in LA_1$, $LI \in L$,

512 ii. $W_1 = \{\}$ (the empty set),

513 iii. for all i , such that $1 \leq i < n$, either

514 (derive-by-Select) for some $A \in LA_i$, $\langle LA_{i+1}, W_{i+1} \rangle = \text{Select}(A, \langle LA_i, W_i \rangle)$, or

515 (derive-by-Transfer) . . . ,

516 (derive-by-Merge) $LA_i = LA_{i+1}$, and the following conditions hold for some A, B :

517 a. $A \in W_i$

518 b. Either A contains B or W_i immediately contains B ,

519 c. $\langle W_i, LA_i \rangle$ is derived by Agree from $\langle W_{i-1}, LA_{i-1} \rangle$, and

520 d. $W_{i+1} = (W_i - \{A, B\}) \cup \{\text{Merge}(A, B)\}$

⁶Wurmbrand (2014) contains the most explicit argument in favour of the latter stance, but see Boeckx (2010) for a broader discussion of the schism.

521 (derive-by-Agree) or $LA_i=LA_{i+1}$ and the following conditions hold for some SO, P, G and F:

522 a. $SO \in W_i$

523 b. SO immediately contains P

524 c. $\text{Probe}(SO,P,F) = \{G\}$

525 d. $W_{i+1} = (W_i - \{SO\}) \cup \{\text{Agree}(SO,P,G,F)\}$

526 Now, lets consider an abstract subderivation of the syntactic object $\{X, Y\}$ where X and Y are lexical item
527 tokens. We start in S_1 , given in (69) with an empty workspace and a lexical array containing at least X and
528 Y.

$$\begin{aligned} 529 \quad (69) \quad S_1 &= \langle W_1, LA_1 \rangle \\ &= \langle \{\}, \{X, Y, Z \dots\} \rangle \end{aligned}$$

530 Next we perform Select twice, to bring X and Y into the workspace.

$$\begin{aligned} 531 \quad (70) \quad S_2 &= \text{Select}(X, S_1) \\ &= \langle \{X\}, \{Y, Z \dots\} \rangle \end{aligned}$$

$$\begin{aligned} 532 \quad (71) \quad S_3 &= \text{Select}(Y, S_2) \\ &= \langle \{X, Y\}, \{Z \dots\} \rangle \end{aligned}$$

533 Under a free Merge grammar, we would, at this point simply Merge X and Y, but this option is not available
534 to us, since derive-by-Merge in (68) requires an Agree step. A Select step is possible here, but that would
535 only postpone our dilemma. We need to perform Agree next.

536 Assuming that X could value Y for feature F—i.e., $\text{Match}(X, Y, F) = 1$ —let’s consider the structural
537 prerequisites. As stated in (68), X and Y must be contained in the same syntactic object SO, which, in turn,
538 must be a member of the workspace. In S_3 , however, both X and Y are members of the workspace, and
539 there is no SO to speak of. No stage S_4 , then, can be derived by Agree.

540 We’ve arrived then at an instance of circularity—every instance of Merge requires a preceding instance of
541 Agree, and every instance of Agree requires a preceding instance of Merge. First Merge, then, is impossible
542 if the definition of a derivation in (68) holds.

543 This is not to say that tying Agree to Merge in some way will always be a dead-end. On the contrary,
544 one of for instance Hornstein’s (2009) critiques of long-distance Agree is that it ties Agree to loosely to
545 Merge. Merge creates the structural conditions for Agree—a point which Local Agree more or less explicitly
546 acknowledges. This leads one to wonder why we consider Merge and Agree to be distinct operations—why
547 Agree is not treated as a reflex of Merge The obvious response to this is that there do seem to be instances
548 of long-distance agreement that do not involve movement. This objection, however, only holds if we rule

549 out the covert movement hypothesis, which that, though it has fallen out of fashion, faces fewer theoretical
550 hurdles than long-distance Agree in my opinion.⁷

551 4.3 Computational Complexity

552 With our definitions of the derivation in (20) and (63) we can give a quantitative estimate of the com-
553 putational complexity of a given derivation, and with that, a measure of the complexity of the grammars
554 overall. As is common in computer science, we will use time-complexity as a proxy. The time complexity
555 of an algorithm is a measurement of how the run-time an algorithm—the length of time it takes to run the
556 algorithm—increases relative to the size of its input.

557 To assess time complexity we must first identify the primitive operation(s) of an algorithm, which we
558 assign a runtime of 1, and the primitive unit of data, which we assign a size of 1. In our derivations the
559 primitive operations are Merge and Select as neither is defined in terms of the other, while Agree is defined
560 in terms of Merge. Each instance of Merge or Select, then, will incur a time cost of 1—the time cost of Agree
561 will be calculated below, and that of Transfer will be ignored. The input size will be a measure of the size
562 of the derived syntactic object which will have two components—the number of lexical item tokens L, and
563 the number of syntactic objects J. The two numbers are related only insofar as they limit each other ($L \leq J$).
564 In practice, though, we will care less about J than the number of derived syntactic objects $M = J - L$. So, the
565 objects in (72) all have different L, J, and M values

- 566 (72) a. A (L=1, J=1, M=0)
567 b. {A, B} (L=2, J=3, M=1)
568 c. {A, {A, B}} (L=2, J=4, M=2)
569 d. {B, {B, {A, B}}} (L=2, J=5, M=3)
570 e. {C, {B, {A, B}}} (L=3, J=6, M=3)

571 Before we assess UG_{Agree} , though, we will consider plain UG to see how we would calculate the run-time
572 of a given derivation. So, for a derivation D, the run-time R will be the sum of μ —the number Merge
573 operations performed in D—and σ —the number of Select operations performed in D.

574 (73) $R_D = \mu + \sigma$ for UG

575 In order to calculate μ and σ , we step through each stage S_n of D, keeping a running tally of each operation.

⁷Strictly speaking, covert A-movement has fallen into disuse. Covert \bar{A} -movement operations, like Quantifier raising, and covert *Wh*-movement in *wh-in-situ* languages, are still considered respectable hypotheses.

$$576 \quad (74) \quad \mu_{S_n} = \begin{cases} 0 & \text{if } n=1 \\ \mu_{n-1} + 1 & \text{if } S_n \text{ is derived by Merge} \\ \mu_{n-1} & \text{otherwise} \end{cases}$$

$$577 \quad (75) \quad \sigma_{S_n} = \begin{cases} 0 & \text{if } n=1 \\ \sigma_{n-1} + 1 & \text{if } S_n \text{ is derived by Select} \\ \sigma_{n-1} & \text{otherwise} \end{cases}$$

578 Since each Select operation in a derivation is associated with a distinct lexical item token, σ for that derivation
 579 will equal L for the derived object. Similarly, each Merge operation in a derivation creates a distinct new
 580 syntactic object, so the μ for for that derivation will equal M for the derived object. Therefore, under UG,
 581 the runtime of the derivation for a syntactic object will be J for that object. So, if we take J to be our
 582 measure of the input size for a derivation, we can see that UG derivations run in what is called linear time.

583 In order to assess UG_{Agree} we need a way to measure the run-time of Agree. For simplicity's sake, I
 584 will not consider the run-times of Value, Match, or Probe, or rather, I will take them to be zero. So, this
 585 simplified Agree, when applied to a lexical item token, returns that token, and when applied to a derived
 586 object, recursively performs Agree on the members of the object and Merges the results. When applied to
 587 an object X then, Agree runs a Merge operation for each derived syntactic object in X.

588 We can define our running tally for Agree in (76) with the final calculation of run-time in (77)

$$589 \quad (76) \quad \alpha_{S_n} = \begin{cases} 0 & \text{if } n=1 \\ \alpha_{n-1} + \mu_{n-1} & \text{if } S_n \text{ is derived by Merge} \\ \alpha_{n-1} & \text{otherwise} \end{cases}$$

590 (77)

$$591 \quad (78) \quad R_D = \mu + \sigma + \alpha \text{ for } UG_{\text{Agree}}$$

592 Since UG_{Agree} does not specify when Agree applies, it allows for derivations where Agree does not apply at
 593 all. These cases will run in linear time, and will be our lower bound for time complexity. As our upper-
 594 bound, consider the cases in which every instance of Merge is followed immediately by an instance of Agree.
 595 Since μ determines the rate of increase for α and μ increases linearly during the course of the, α will increase
 596 quadratically, and therefore, R will increase quadratically relative to the number of stages. The run-time of
 597 such a derivation is demonstrated in figure 4. Since the number of stages here is proportional to the size of
 598 the derived object, the time-complexity of this type of derivation is also quadratic.⁸

⁸More precisely, the run-time of this type of derivation as a function of object size is resembles the triangular number series

Figure 4: The run-time of a derivation in UG_{Agree} following a Select-Merge-Agree cycle

599 Of course, the Select-Merge-Agree cycle that this assumes is not a realistic characterization of an actual
600 syntactic derivation for a number of reasons. For one, it represents a derivation with only External Merge,
601 while the overwhelming evidence suggests that actual expressions are always derived with a mix of internal
602 and external. Also, it is likely not the case that every instance of Merge is followed by an instance of
603 Agree. For example, cyclic movement through non-licensing positions could be argued to involve Merge but
604 not Agree. Even including all of these caveats, the facts that the run-time of a single instance of Agree
605 is proportional to the size of the object it operates on and that the size of that object steadily increases
606 throughout any derivation mean that no derivation which includes more than one non-consecutive instance
607 of Agree will operate in linear-time.

608 4.4 Agree and the NTC

609 One of the theorems of C&S’s formal grammar is the No Tampering Condition defined by Chomsky (2007,
610 p. 8) as follows: “Suppose X and Y are merged. Evidently, efficient computation will leave X and Y unchanged
611 (the No-Tampering Condition NTC). We therefore assume that NTC holds unless empirical evidence requires
612 a departure from [the strong minimalist thesis] in this regard, hence increasing the complexity of UG.” C&S’s
613 formulation of NTC, which they prove as a theorem of UG, is given in (79).

614 (79) For any two consecutive stages in a derivation $S_1 = \langle LA_1, W_1 \rangle$ and $S_2 = \langle LA_2, W_2 \rangle$,
615 for all A contained in W_1 , A is contained in W_2 .

(1).

$$(1) \sum_{i=0}^n \frac{i(i+1)}{2}$$

616 Since the effect of every form of Agree defined in this paper is to replace all instances of some lexical item
617 token G in a workspace with a distinct item G' , Agree violates NTC by design. The increased computational
618 complexity of UG_{Agree} discussed above, then, is predicted by Chomsky’s conjecture that the NTC is linked
619 to computational efficiency. There are essentially two ways of dealing with this result—either we take the
620 approach that C&S take with Transfer and modify Agree so that it does not violate NTC, or we argue that
621 “empirical evidence requires a departure from” NTC. I will discuss each of these options in turn below.

622 4.4.1 NTC-Respecting Agree

623 A straightforward way of constructing an Agree operation that respects the NTC is to formally separate the
624 content of a derived expression from its structure in some way with Merge manipulating the structure and
625 Agree manipulating the content. A stage of the derivation, then would consist of a lexical array, a workspace,
626 and ledger as in the definition in (80)

627 (80) A stage is a triple $S = \langle LA, W, L \rangle$, where LA is a lexical array, W is a set of syntactic objects, and
628 L is a set of pairs of lexical item tokens. We call W the workspace of S and L the ledger of S .

629 Rather than modifying lexical item tokens in place, Agree would add a pair $\langle LI_k, LI'_k \rangle$, where LI_k is a lexical
630 item token contained in the workspace and LI'_k is the result of Valuing LI_k for some feature. The ledger,
631 then, postpones the tampering of Agree, either until Transfer, or until the SM and/or the CI system and
632 thereby rescues the NTC.

633 This sort of move also fixes a number of issues already discussed regarding Agree. A version of agree
634 that respects NTC does not alter the workspace—it merely constructs an ordered pair and adds it to the
635 ledger. It does not take apart and put back together an already constructed syntactic object, as standard
636 Agree as defined in (51) does. Therefore it does not need to be recursively defined, and it does not need to
637 refer to Merge in its definition. As a result, it does not carry the same time-costs as standard Agree.

638 This improvement aside, however, it also lays bare the fact that Agree as a syntactic-derivational operation
639 is fundamentally redundant. The prerequisites for Agree are a structural relation (Search) and content
640 relation (Match) between two lexical item tokens. So, suppose P and G are lexical item tokens and, for some
641 feature F , $\text{Match}(P,G,F)=1$. Further suppose that stage S_n in derivation D is derived by $\text{Merge}(P, X)$, where
642 X contains G and no lexical item token H , such that $\text{Match}(P,H,F)=1$. At this point, our prerequisites
643 are met and we can perform Agree, but supposing instead we derive stages S_{n+1} and S_{n+2} by Selecting
644 and Merging another lexical item token. By the NTC, the object $\{P, X\}$ is contained in the root object of
645 S_{n+2} , and therefore all of the structural and content relations that held at S_n still hold at S_{n+2} including

646 the prerequisites for P to Agree with G for F.⁹ By extension, we can continue to postpone Agree at least
647 until the next instance of Transfer without losing the prerequisites for Agree. It seems, then, that, while we
648 can certainly define Agree so that it respects NTC, if we have NTC, we don't need Agree as a derivational
649 operation.

650 4.4.2 Agree instead of the NTC?

651 Even as stated by Chomsky (2007), the NTC is not an absolute law akin, say, to the law of non-contradiction.
652 Rather, he proposes that we assume the NTC “unless empirical evidence requires a departure from [the strong
653 minimalist thesis] in this regard.” In one sense, this is a very low bar, since NTC is a universal statement,
654 which only requires a single counterexample to invalidate. In practice though, it is far from obvious what
655 sort of evidence would count as counterexample.

656 The relative ubiquity of morphological agreement, for instance, might seem to be the sort of evidence we
657 need, but it is not sufficient to invalidate NTC. Consider, as a parallel, linear order. It is a plain fact that
658 external linguistic expressions have linear order, yet that linear order is still assumed to be absent in the
659 grammar—at least in standard Merge-based grammars. Yet, as Chomsky (2020) citing McCawley (1968)
660 points out, adverbs like *respectively*, which depend on linear order for their interpretation, provide evidence
661 that conjunction structures have inherent linear order.

662 (81) Beth and Sara met Hanako and Máire respectively.

663 a. = Beth met Hanako and Sara met Máire.

664 b. \neq Beth met Máire and Sara met Hanako.

665 What we need, then, is evidence that standard Agree is occurring in a derivation interspersed with
666 Merge. Preminger (2014) argues that we have exactly such evidence in the interrelation of morphological
667 case, φ -agreement, and subject position. The form of the argument is given in (82)

668 (82) a. Morphological case feeds φ -agreement in quirky-subject languages.

669 b. Φ -agreement feeds movement to canonical subject in non-quirky-subject languages.

670 c. The functioning of the grammar is uniform across languages (The Uniformity Principle).

671 d. **Therefore**, morphological case and φ -agreement precede movement to subject.

672 e. **Therefore**, morphological case and φ -agreement are part of the narrow syntax.

673 The argument is logically sound, but it depends on an analysis of the evidence that is plausible, but not
674 the only possible analysis. That is, it depends of the truth of the first two premises, which are empirical

⁹See theorems 2 and 3 in Collins and Stabler (2016).

675 statements. Despite being empirical statements, though, they depend on two theoretical notions—“quirky
676 subjects” and “canonical subject position”—to even be coherent. I will take for granted that the term
677 “quirky subject” is coherent, and focus on “canonical subject position.”¹⁰

678 One property of canonical subject position that Preminger is clear about is that it is syntactic—he
679 says of movement to canonical subject position that it is “clearly syntactic (since it creates new binding
680 configurations, for example)” (p177) and that it “is a syntactic process par excellence” (p184). We further
681 know, based on the second premise of (82), which Preminger claims as an empirical result, that canonical
682 subjects in non-quirky-subject languages should always trigger φ -agreement. Since this latter requirement is
683 an empirical claim, though, it should not be too directly tied to our definition lest our reasoning be circular.
684 We can construct our definition by applying these two desiderata to some representative data.

685 Our representative data is given in (83), where the underlined subexpression is could be or has been
686 considered a subject in English.

- 687 (83) a. The city is bustling.
688 b. There seem to be unicorns in my house.
689 c. The dog running down the street was quite a sight.
690 d. They seemed t to leave.
691 e. I expect t/PRO to leave shortly.
692 f. We believed them to be a capable team.

693 I believe that it is quite safe to label *the city* in (83a) as a canonical subject¹¹—it is the specifier of TP and
694 it triggers φ -agreement on the finite auxiliary. On the other hand, the existential associate *unicorns* in (83b)
695 is likely not in a canonical subject position.¹² In fact, existential associates not being in canonical subject
696 position gives force to the second premise of (82)—in order for φ -agreement to feed movement to canonical
697 subject position, agreement must be necessary but not sufficient for movement and existential clauses show
698 this only if we assume that their associates are not (possibly covertly) in canonical subject position.¹³

699 This leaves us with non-finite subjects in (83c) to (83f). In each of these cases, the underlined expression
700 could reasonably be said to be in a subject position, and to have moved there, yet there is no apparent
701 φ -agreement associated with that move. We could reasonably reject *the dog* in (83c) as a canonical subject,

¹⁰It should be noted that the modifiers “quirky” and “canonical” are both subjective in nature, suggesting that the phenomena that they refer to have not yet been given a theoretical explanation.

¹¹We might call it the canonical canonical subject.

¹²See Hornstein (2009, pp. 130–134), though, for discussion to the contrary.

¹³The expletive *there* in (83b) seems to be in canonical subject position—if *unicorns* was there it would be the canonical subject—but it does not trigger φ -agreement. This, however, does not contradict (82b), which links φ -agreement with movement to canonical subject position, not to the position itself, if we assume that expletives are inserted in subject position, not moved there.

702 since it is not a specifier to a TP, leaving us with the null subjects in (83d) to (83e) and the ECM subject
703 in (83f). In a summarizing table, though, Preminger (2014, p. 164) seems to assert that, in English, only
704 nominatives are candidates for movement to canonical subject. This would rule out traces/PRO and ECM
705 subjects as canonical subjects.

706 Canonical subject position, then, seems to refer to the specifier of finite T, at least in English. Assuming
707 such a position can be defined well enough to support generalizations such as Preminger’s premises,¹⁴ the
708 Uniformity Principle—Preminger’s third premise—demands that we treat movement to the specifier of finite
709 T as a grammatical process, which, in the current system, means treating it as a derivational procedure
710 distinct from Merge, Select, Agree and Transfer. So, if we keep strictly to the theory assumed in this paper,
711 Preminger’s argument does not go through.¹⁵

712 To recap, Preminger’s argument as given in (82), while logically sound, rests on the assumption that
713 movement to canonical subject position is a bona fide syntactic operation, distinct from other types of
714 movement. This assumption would be a departure from the theory assumed here, which takes all movement
715 operations to be instances of Merge. Preminger’s conclusion, that agreement takes place in the syntax taken
716 with my argument above that Agree violates the NTC, implies the conclusion that the NTC should be at
717 least weakened¹⁶—another departure from the theory. It would seem, then, that one departure from theory
718 begets other departures—a result that is far from surprising and, in fact, indicates the internal unity of the
719 theory of grammar assumed here. More importantly, Preminger’s argument, the most explicitly fleshed out
720 empirical argument in favour of Agree as a syntactic operation, should not be taken as a falsification of NTC
721 or SMT.

722 5 Concluding remarks

723 The task of formalizing a theoretical conjecture occupies an odd place in the sciences. While it does generally
724 not bring anything new to the table, it does give us the opportunity to objectively assess the validity and

¹⁴Chomsky (2013), for instance, argues that “specifier” is not definable in a theory based on simplest Merge, such as the one assumed in this paper. This is not strictly true but, whereas “specifier” was trivially definable in a system like X-Bar, which takes labelling as a primitive, any definition of “specifier” in the present system would likely consist of the coordination of multiple predicates.

¹⁵It might be argued that the theory assumed here cannot account for the range of data that Preminger discusses and should, therefore, be rejected. Such an objection, I would argue, mistakes entirely the nature of scientific, and more broadly rational, inquiry. While a full airing of this argument is beyond the scope of this paper, I will merely ask the reader to consider two points:

1. No scientific theory is or has ever enjoyed complete empirical coverage, even within its own domain.
2. Despite common narratives to the contrary, progress in the sciences is generally led by theoretical progress rather than the collection of novel data.

¹⁶Preminger (2018) builds on these results to argue against the SMT. If we do not accept his 2014 argument, we do not have to accept his later argument that depends on it,

725 theoretical prospects of various informal proposals. By formalizing various proposals for Agree as a syntactic
726 operation, we can see that what often is shown as a simple curved arrow on tree diagrams is actually a
727 rather complicated computational operation. Not only is this complexity apparent simply from the size
728 of the formal definition compared, say, to that of Merge, but it can, in a way, be measured and given an
729 objective evaluation—in section 4, I showed that derivations with Agree were in a different complexity class
730 than those without Agree, and that Agree is incompatible with the NTC, a central minimalist tenet. I
731 further showed that, while the set of syntactic objects, as defined by Collins and Stabler (2016), is closed
732 under Merge, it is not closed under Agree without making some ad-hoc modifications to our theory.

733 In its current state, then, Agree should not be taken for granted. This, however, leaves the theory in an
734 awkward position—the phenomena that Agree is supposed to explain appear to be real and rather ubiquitous,
735 but our tool for explaining them is not yet ready. If we are engaged in rational inquiry (*i.e.*, science) then
736 we should not be surprised to find ourselves in such a position. It does not mean that its time to throw up
737 our hands and discard our current theory. It means that we have plenty of work left—an enviable position
738 to be in.

739 Acknowledgements

740 This work was first presented at the 4th annual Dog Days syntax/morphology/semantics workshop at the
741 University of Toronto in 2015. I am grateful for the comments I received then and there. I am also grateful
742 for helpful comments on earlier drafts from Christopher Collins, Andrew McInerney, Omer Preminger, and
743 Dmitrii Zelenskii. The writing of this paper was supported by the Canada Recovery Benefit.
